

Shisha/hookah waterpipe tobacco smoking

What is it and is it harmful?

What is it?

Waterpipe tobacco smoking involves using a single or multi-stemmed instrument to smoke flavoured or non-flavoured tobacco.

Smoke passes through water or other liquids before reaching the user.

Is it harmful?

Those smoking shisha or hookah are exposed to much higher levels of carbon monoxide (CO) and other carcinogens such as polycyclic aromatic hydrocarbons (PAH) than those who smoke cigarettes.

Waterpipe smoke also contains nicotine and has the potential to be addictive.

Second-hand smoke from waterpipes is just as dangerous to others as smoke from cigarettes.

Smoking waterpipes is also associated with multiple long-term adverse health outcomes for example:

- elevated heart rate and blood pressure
- impaired lung function
- lung cancer
- periodontal disease
- low birth weight
- COPD
- cardiovascular disease.
